

Exp-1:

Aim : Building a portfolio website

Tech stack : Html,js,css

Summary of implementation :

Tools used

- Plain **HTML5** — no framework, no build step
- Plain **CSS3** — custom properties (CSS variables) for the color/type tokens, CSS Grid & Flexbox for layout, @media queries for responsiveness
- Plain **JavaScript (vanilla)** — no libraries
- **Google Fonts**: Space Grotesk (headings), Inter (body text), JetBrains Mono (terminal/code bits)

How it's built

1. **index.html** — the content and structure only: nav, hero, about, experience/education, projects, skills, contact, footer. Each section is a plain `<section>` with a `.container` div to constrain width.
2. **style.css** — a token system at the top (`:root { --bg, --ink, --accent, ... }`) so colors/fonts are defined once and reused everywhere. Below that, one block of rules per section, plus responsive breakpoints at the bottom that collapse the multi-column grids to single columns on smaller screens, and a hamburger menu that only appears under 720px.
3. **script.js** — three small independent pieces:
 - **Mobile nav toggle**: adds/removes an open class on the nav list when the hamburger button is clicked.
 - **Typing effect**: a `setTimeout` loop that types and deletes each role line character-by-character in the terminal box (skipped if the user has "reduce motion" turned on).
 - **Scroll reveal**: uses `IntersectionObserver` to add an in-view class to cards/timeline items as they scroll into view, which CSS then fades/slides in.

Outputs:

Observations :

1.Js is good for rendering dynamically using dom

2.Dom takes more time to render

Result :

Got hands on with the html,css,js
